

# Visualizing the Geography of Genetic Variants

Joseph H. Marcus<sup>\*1</sup> and John Novembre<sup>\*1</sup>

<sup>1</sup>Department of Human Genetics, University of Chicago, Chicago, IL, USA

## Abstract

One of the key characteristics of any genetic variant, beyond its potential phenotypic effects or its global frequency, is its geographic distribution. The geographic distribution of a genetic variant can shed light on where the variant first arose, in what populations it has spread to, and in turn how migration, genetic drift, and natural selection have acted on the variant. Collectively the geographic distribution of many genetic variants can inform on how populations have been related through time (e.g. levels of gene flow and divergence). The distribution of a genetic variant can also be informative background knowledge for medical/clinical geneticists. As a result, visual inspection of geographic maps for genetic variants is common practice in genetic studies. Here we develop an interactive visualization tool for illuminating the geographic distribution of genetic variants. Through an efficient SQL database, REST API and dynamic front-end the *Geography of Genetic Variants (GGV)* browser rapidly provides maps of allele frequencies in populations distributed across the globe.

## 16 Introduction

17 Genetics researchers often face the problem that they have identified one or many genetic variants of interest (e.g. from a genome-wide association, eQTL, or pharmacogenomic study) and would like to know the  
18 geographic distribution of the variant. For example, the researcher may hope to address: 1) implications for  
19 genomic medicine (e.g. is a risk allele geographically localized to a certain patient population?); 2) design  
20 of follow-up studies (e.g. what population should be studied to observe variant carriers?); or 3) the biology  
21 of the variant in question (e.g. does the variant correlate with a known environmental factor in a manner  
22 suggestive of some geographically localized selection pressure?) ROSENBERG *et al.* (2010); NOVEMBRE and  
23 DI RIENZO (2009); COOP *et al.* (2010). A simple geographic map of the distribution of a genetic variant can  
24 be incredibly insightful for these questions.  
25

26 Contemporary population genetics researchers are also faced with the challenge of large, high dimensional  
27 datasets. For example, is not uncommon for a researcher in human genetics to have a dataset comprised of  
28 thousands of individuals measured at hundreds of thousands or even millions of single nucleotide variants  
29 (SNVs). One common approach to visualizing such high-dimensional data is to compress the SNV dimensions  
30 down to a small number of latent factors, using a method such as principal components analysis PRICE *et al.*  
31 (2006); PATTERSON *et al.* (2006), or a model-based clustering method such as STRUCTURE PRITCHARD  
32 *et al.* (2000) or ADMIXTURE ALEXANDER *et al.* (2009). While these approaches are extremely valuable,  
33 researchers can use them too often without inspecting the underlying variant data in more detail. A natural  
34 approach to gaining more insight to the overall structure of a population genetic dataset is to visually inspect  
35 what geographic patterns arise in allele frequency maps.

36 Unfortunately, generating geographic allele frequency maps is time-consuming for the average researcher  
37 as it requires a combination of data wrangling methods FURCHE *et al.* and map making techniques that  
38 are unfamiliar to most. Our aim here is to produce a tailored system for rapidly constructing informative  
39 geographic maps of allele frequency variation.

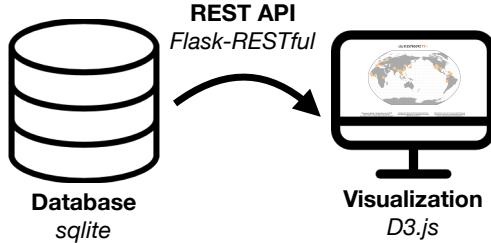

40 Our work is inspired by past tools such as the ALFRED database RAJEEVAN *et al.* (2011) and the  
41 maps available on the HGDP Selection browser PICKRELL *et al.* (2009). One of us (J.N.) developed the  
42 scripts for the HGDP Selection Browser maps using The Generic Mapping Tools (GMT) WESSEL *et al.*  
43 (2013), a powerful system of geographic plotting scripts for making static plots. The plots from the HGDP  
44 Selection Browser have proved useful, and have appeared in research articles e.g. PICKRELL *et al.* (2009),  
45 COOP *et al.* (2009), books e.g. DUDLEY and KARCZEWSKI (2013), and have been ported and made available  
46 on the UCSC Genome Browser (available under the HGDP Allele Freq track of the browser). Reference  
47 datasets for population genetic variation have greatly expanded since the release of the HGDP Illumina  
48 650Y dataset LI *et al.* (2008) that formed the basis of the HGDP Selection Browser maps. The most notable  
49 advance is the publication of the 1000 Genomes Phase 3 data CONSORTIUM *et al.* (2015) though additional  
50 datasets are continually coming online MEYER *et al.* (2012); LAZARIDIS *et al.* (2014). In addition, novel  
51 approaches for data visualization have become more widely available. In particular, web-based visualization  
52 tools, such as Data Driven Documents (D3.js), offer useful methods for interactivity, the advantages of  
53 software development in modern web-browsers, a large open-source development community, and ease of  
54 sharing BOSTOCK *et al.* (2011).

55 Taking advantage of these recent advances, we aim to address the significant visualization challenges that  
56 are inherit in the production of geographic allele frequency maps, including dynamic interaction, display  
57 of rare genetic variation, and representation of uncertainty in estimated allele frequencies due to variable  
58 sample sizes.

## 59 Fundamental Approach

60 The Geography of Genetic Variants browser (GGV) uses the scalable vector graphics and mapping utilities  
61 of D3.js BOSTOCK *et al.* (2011) to generate interactive frequency maps, allowing for quick and dynamic  
62 displays of the geographic distribution of a genetic variant.

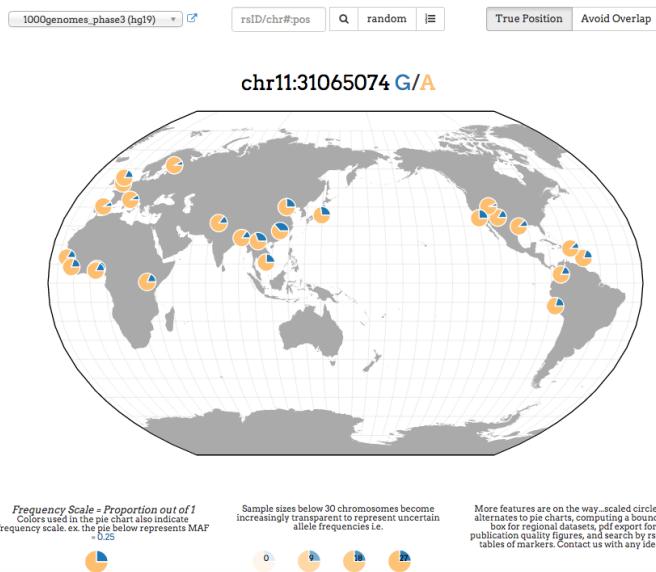

63 In order to allow for easy access to large commonly used public genomic datasets, such as the 1000

**Figure 1:** Schematic diagram of the Geography of Genetic Variants (GGV) browser. We compute minor allele frequencies from publicly available population genetic datasets from the 1000 Genomes Project, Human Genome Diversity Project (HGDP) and Population Reference Sample (POPRES). These allele frequencies are stored in a SQL database along side with geographic coordinates associated with each population. The front-end visualization was created using D3.js and accesses allele frequency and population meta-data from a REST API implemented in the python library flask.

64 Genomes project CONSORTIUM *et al.* (2015), Human Genome Diversity project LI *et al.* (2008), we have  
 65 developed an SQL database and REST API for querying allele frequencies by chromosome and position, by  
 66 reference SNP identifier SHERRY *et al.* (2001), or randomly sampled SNPs [Figure 1].

67 The front-end of the project is a browser-based visualization application that displays the geographic map  
 68 of a particular variant and provides legends for the map and various boxes to allow users to query different  
 69 datasets or choose visualization options. While many applications require inspection of the distribution of  
 70 a specific variant, from our experience, it can be very helpful to quickly view the geographic distribution  
 71 of several randomly chosen variants to quickly gain a sense of structure in a dataset. For instance, in data  
 72 with deep population subdivision, it is obvious in the consistent patterns of differentiation observed across  
 73 markers. We also expect this will be useful in teaching contexts as it provides a highly visual way for learners  
 74 to understand human genetic variation.

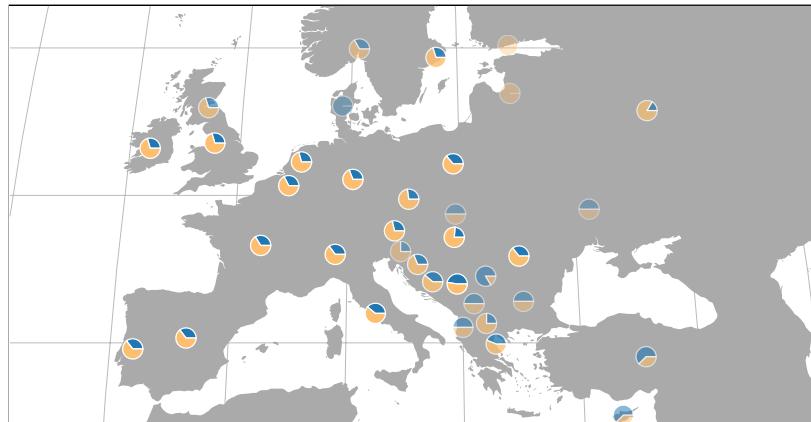

**Figure 2:** Example screenshot from the Geography of Genetic Variants browser using the CONSORTIUM *et al.* (2015) data. Each pie chart represents a population with the blue slice of the pie displaying the frequency of the global minor allele and the yellow slice of the pie displaying the frequency of the global major allele in each population.

75 After a query, the GGV displays the frequency of a variant in a given population as a pie chart where  
76 each slice represents minor and major allele frequencies. Pie charts are displayed as points positioned at the  
77 population's region of origin and the projection / map-view is chosen based off of the geographic configuration  
78 of populations in a given dataset [Figure 2].

## 79 Representing uncertainty in frequency data

80 One under-appreciated problem with allele frequency maps is that not all data points have equal levels of  
81 certainty. For some locations, sample sizes are small, and the reported allele frequency may be quite far from  
82 the true population frequency due to sampling error. To address this issue, we use varying transparency in a  
83 population's pie chart: sampled populations with higher levels of sampling error (i.e.  $n < 30$ ) are made more  
84 transparent, and hence less visible on the map [Figure 3].

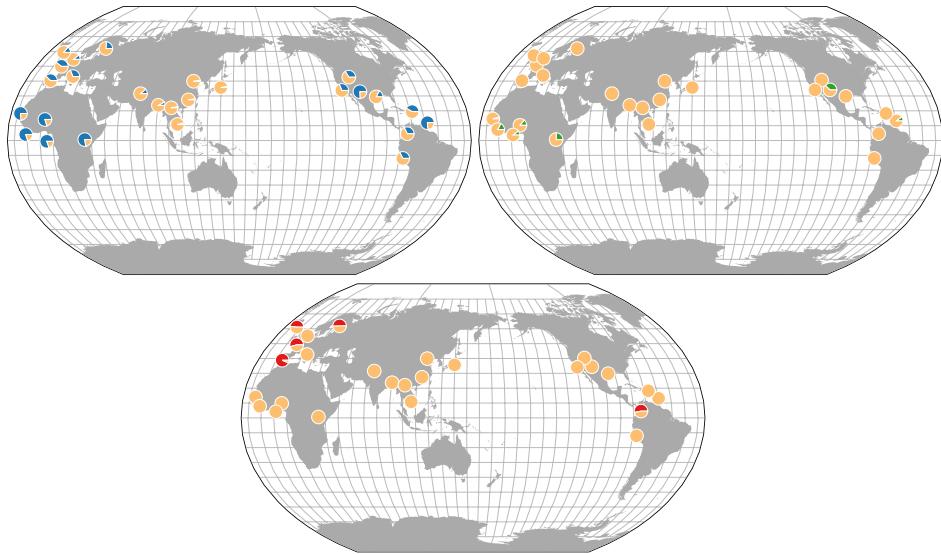

**Figure 3:** Example map from the Geography of Genetic Variants browser displaying the use of varying transparency of population pie charts to represent uncertainty in allele frequencies. The transparency is scaled in proportion to the number of observed chromosomes in each population for a particular variant. The frequency data and population identifiers are from NOVEMBRE *et al.* (2008).

## 85 Representing rare variants in frequency data

86 An additional challenge is that allele frequencies between variants often differ greatly, sometimes by orders  
87 of magnitude in a single dataset. This has not been an pervasive problem until recently, as most population  
88 genetic samples were based on genotype arrays, which biased towards variants that are common in human  
89 populations (5-50 % in minor allele frequency). With the advent of next generation sequencing technologies,  
90 novel array designs focusing on rarer variants, and large samples of thousands of individuals, it is now  
91 common for datasets to contain rare variants CONSORTIUM *et al.* (2015); NELSON *et al.* (2012); TENNESSEN  
92 *et al.* (2012). In current visualization schemes, such as the HGDP Selection Browser, rare variants would be  
93 represented as narrow slivers in a pie chart, nearly invisible to the naked eye.

94 To address this challenge we re-scale frequencies for rare variants, so that small frequencies become  
95 visible. Specifically, we use a frequency scale that is indicated in a legend below the map, and redundantly  
96 by using color, that indicates the scale for the frequencies displayed [Figure 4]. Much like scientific notation,  
97 this allows a wide range of frequencies to be displayed. [xxJN: I'd like us to use the example maps, plus a  
98 figure that shows a table of the colors being used and how they translate. I have a figure I've used in talks  
99 that should work. xxJM: see latex table in progress]

**Figure 4:** Example maps from the Geography of Genetic Variants browser displaying the use of frequency scales for more expressive representations of rare variation on geographic maps. The blue pie charts convey a give minor allele frequency out of 100 percent, the green out 1 percent, and the red out of .01 percent. The data are from CONSORTIUM *et al.* (2015).

## 100 Additional features of the interface

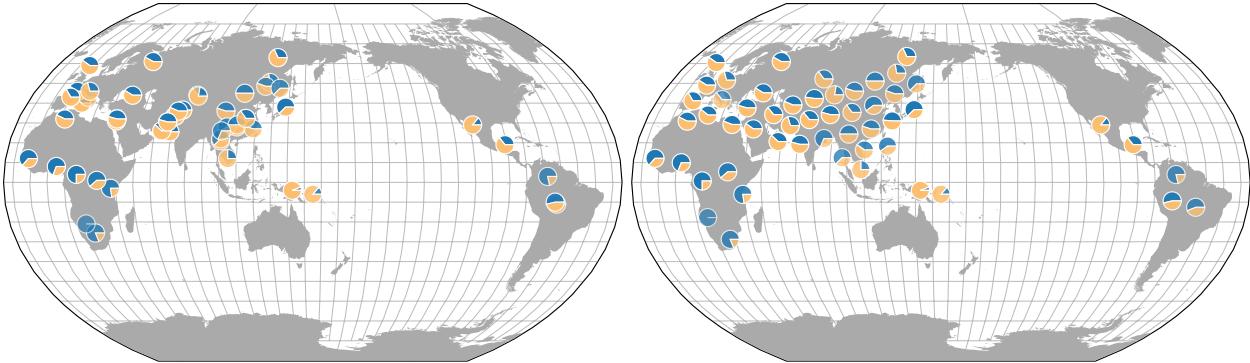

101 In many datasets where populations are sampled densely in geographic space, one problem is that allele  
 102 frequency plots begin to overlap each other and obscure information. To address this issue, we use force-  
 103 directed layouts of the populations such that no two points are overlapping each other, and yet the points  
 104 will be pulled towards their true origins [Figure 5]. Also, by hovering the mouse cursor over any population,  
 105 a user can see the population labels and precise frequency information.

## 106 Access to the underlying frequency data

107 To provide an interface to the population minor allele frequency data stored in the SQL database we use a  
 108 REST API implemented in the python library Flask-RESTful @citeXXX. The front-end D3.js visualization  
 109 uses the API to obtain the data, though users can also interface with it directly. For the front-end, GET  
 110 requests are submitted to the database via HTTP, returning json formatted allele frequency data and the  
 111 meta-data associated with each population and genetic variant e.g. latitude, longitude, population label,  
 112 sample size, and frequency scale. Genetic variants can be queried by chromosome position, rsid, or randomly.  
 113 Example HTTP requests and json response can be seen in Examples 1,2,3 (below).

## 114 Caveats

115 A major challenge of using a geographic representation of genetic variation in humans is that the samples  
 116 must be associated with a geographic location. While doing so is generally immensely helpful, it has inherent  
 117 complexity and limitations. For example, practitioners must make choices regarding representing where an  
 118 individual was sampled for the study (e.g. the city of a major research center) or choosing a location that is  
 119 more representative of an individual's ancestral origins (e.g. as determined in practice by the birthplaces of  
 120 recent ancestors, such as grandparents). We do not proscribe a general solution to this problem and instead

**Figure 5:** Example maps from the Geography of Genetic Variants browser displaying the use of a force directed layout to limit visual clutter when many populations overlap in geographic position. The left map shows the original population locations while the right shows the application of the force directed layout.

121 use a set of locations for each dataset that is based on those used by the initial analysts of the data. A future  
 122 feature will allow alternative location schema to be used for the populations in a dataset.

## 123 Conclusion

124 By allowing rapid generation of allele frequency maps, we hope to facilitate the interpretation of variant  
 125 function and history by practicing geneticists. We also hope the ability to query random variants from major  
 126 human population genetic samples will allow students to appreciate the structure of human genetic diversity  
 127 in a more approachable and intuitive form than alternative visualizations.

128 We also envision a variety of future extensions to the GGV that would allow for further dissection  
 129 of geographical structure in large-scale population genomic datasets. Providing an interactive means of  
 130 browsing neighboring variant sites near a SNP of interest would offer a unique view into patterns of linkage  
 131 disequilibrium around that focal SNP which would be widely relevant to medical geneticist conducting  
 132 genome-wide association studies as well as population geneticists interested in signatures of selection. We  
 133 imagine incorporating a chromosomal browser such as jbrowse or a visualization inspired by the UCSC  
 134 Genome Browser within the GGV would be greatly utilized by researchers and educators alike.

135 The constellation of common single-nucleotide polymorphism (SNP) alleles carried by an individual  
 136 can provide some insight to the geographic origins of their recent ancestors. More recently, the increasing  
 137 availability of data on rare variants is opening up new opportunities for ancestry inference. Rare variants are  
 138 particularly informative for ancestry as they tend to be localized in small geographic regions because they  
 139 have arisen recently in human history and have had little time to spread across populations through migration  
 140 events NELSON *et al.* (2012); MATHIESON and MCVEAN (2014). By assessing the geographic distribution  
 141 of rare variants carried by an individual one can gain information about their ancestry (e.g. ??). In these  
 142 applications, geographic maps of the genetic variants an individual carries can be useful and informative.  
 143 We imagine developing tools to upload personal genetic data from companies such as from 23andMe or  
 144 AncestryDNA would allow users to visualize the set of rare variants they carry and could be of wide interest  
 145 to the public. In order to achieve this goal we plan to extend the ability of the GGV API to query and return  
 146 data from thousands of genetic variants at a time.

## 147 Acknowledgements

148 Support for this work was provided by the NIH-BD2K initiative (1U01 CA198933-0). The authors would  
 149 also like to thank members of the Novembre Lab for supportive conversations.

## 150 Example 1: Query by rsid

```
151 http://popgen.uchicago.edu/ggv_api/freq_table?data="1000genomes_phase3_table"&rsID=rs1834640
152 [
153   {
154     "alleles": ["A", "G"],
155     "pos": [-15.310139, "13.443182"],
156     "pop": "GWD",
157     "nobs": "226",
158     "xobs": "17",
159     "freqscale": 1,
160     "freq": [0.0752212389381, 0.9247787610619],
161     "chrom_pos": "15:48392165",
162     "rawfreq": 0.0752212389381
163   },
164   ...
165 ]
```

## 166 Example 2: Query by chromosome position

```
167 http://popgen.uchicago.edu/ggv_api/freq_table?data="1000genomes_phase3_table"&chr=14&pos=37690093
168 [
169   {
170     "alleles": ["G", "A"],
171     "pos": [-15.310139, "13.443182"],
172     "pop": "GWD",
173     "nobs": "226",
174     "xobs": "0",
175     "freqscale": 0.01,
176     "freq": [0.0, 1.0],
177     "chrom_pos": "14:37690093",
178     "rawfreq": 0.0
179   },
180   ...
181 ]
```

## 182 Example 3: Random query

```
183 http://popgen.uchicago.edu/ggv_api/freq_table?data="1000genomes_phase3_table"&random_snp=True
184 [
185   {
186     "alleles": ["T", "C"],
187     "pos": [-15.310139, "13.443182"],
188     "pop": "GWD",
189     "nobs": "226",
190     "xobs": "0",
191     "freqscale": 0.01,
192     "freq": [0.0, 1.0],
193     "chrom_pos": "5:42452893",
194     "rawfreq": 0.0
195   },
196   ...
```
